Which filter for which water?

A typical head-works uses a first stage to take out the bulk of the dirt and a second stage to protect the drippers. Tell us your water source and flow and we will size the system for you.

Sand media filter

Deep sand bed for dam, river and canal water with algae and organic matter (over 10 mg/L). Usually the first stage.

Disc filter

Stacked grooved discs for drip and micro systems; traps fine and fibrous particles, 40–200 micron.

Screen filter

Stainless-steel screen, 10–500 mesh; economical final filtration for cleaner water.

Hydrocyclone

Spins out over 80% of suspended sand; the first stage for boreholes and sandy water.

90%

fewer blockage failures

65%

lower labour cost

25%

lower maintenance cost

Typical results reported by the manufacturer for automatic filtration compared with manual systems.
